

Automated Software Verification and Synthesis in Unmanned Aerial Vehicles

Lucas Cordeiro
School of Computer Science
lucas.cordeiro@manchester.ac.uk

Outline

Verification and Synthesis Overview

Vision for Future Research

**Synergies and Potential
Collaboration**

Verifying Embedded Software in UAV is Hard

- Unmanned Aerial Vehicles (UAVs) are **systems-of-systems** that couple their **cyber** and **physical** components

Security Challenges in UAVs

- Security vulnerabilities can lead to **drastic consequences**

Boeing Unmanned Little Bird H-6U

Attacked by **rogue camera software** and by a **virus** delivered through a compromised USB stick

- Security raises **additional challenges**
 - Vulnerability analysis (software connected with hardware)
 - Remote accessibility (device authentication, access control)
 - Patch management (vendors might be long gone)
 - Attacks from physical world (GPS spoofing and replay attack)

Security Vulnerabilities

```
int getPassword() {  
    char buf[4];  
    gets(buf);  
    return strcmp(buf, "SMT");  
}
```

```
void main(){  
    int x=getPassword();  
    if(x){  
        printf("Access Denied\n");  
        exit(0);  
    }  
    printf("Access Granted\n");  
}
```

- What happens if the user enters "SMT"?
- On a Linux x64 platform running GCC 4.8.2, an input consisting of 24 arbitrary characters followed by], <ctrl-f>, and @, will bypass the "Access Denied" message
- A longer input will run over into other parts of the **computer memory**

Bounded Model Checking (BMC)

Basic idea: check negation of given property up to given depth

- Transition system M unrolled k times
 - for programs: loops, recursion, ...
- Translated into verification condition ψ such that
 ψ **satisfiable iff φ has counterexample of max. depth k**

BMC has been applied successfully to
verify HW and SW

Ensure Software Security in UAVs

- BMC techniques can be used to ensure **software security**

Requirements	Definition
Availability	services are accessible if requested by authorized users
Integrity	data completeness and accuracy are preserved
Confidentiality	only authorized users can get access to the data

Critical Software Vulnerabilities

- Null pointer dereference

```
int main() {  
    double *p = NULL;  
    int n = 8;  
    for(int i = 0; i < n; ++i )  
        *(p+i) = i*2;  
    return 0;  
}
```

A NULL pointer dereference occurs when the application dereferences a pointer that it expects to be valid, but is NULL

Scope	Impact
Availability	Crash, exit and restart
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands

Critical Software Vulnerabilities

- Null pointer dereference
- Double free

```
int main(){  
    char* ptr = (char *)malloc(sizeof(char));  
    if(ptr==NULL) return -1;  
    *ptr = 'a';  
    free(ptr);  
    free(ptr);  
    return 0;  
}
```

The product calls *free()* twice on the same memory address, leading to modification of unexpected memory locations

Scope	Impact
Integrity Confidentiality Availability	Execute Unauthorized Code or Commands

Critical Software Vulnerabilities

- Null pointer dereference
- Double free
- Unchecked Return Value to NULL Pointer Dereference

```
String username = getUsername();  
if (username.equals(ADMIN_USER)) {  
    ...  
}
```

The product does not check for an error after calling a function that can return with a NULL pointer if the function fails

Scope	Impact
Availability	Crash, exit and restart

Critical Software Vulnerabilities

- Null pointer dereference
- Double free
- Unchecked Return Value to NULL Pointer Dereference
- Division by zero
- Missing free
- Use after free
- APIs rule based checking

Satisfiability Modulo Theories

SMT decides the **satisfiability** of first-order logic formulae using the combination of different **background theories**

Theory	Example
Equality	$x_1 = x_2 \wedge \neg (x_1 = x_3) \Rightarrow \neg (x_1 = x_3)$
Bit-vectors	$(b \gg i) \& 1 = 1$
Linear arithmetic	$(4y_1 + 3y_2 \geq 4) \vee (y_2 - 3y_3 \leq 3)$
Arrays	$(j = k \wedge a[k] = 2) \Rightarrow a[j] = 2$
Combined theories	$(j \leq k \wedge a[j] = 2) \Rightarrow a[i] < 3$

Software BMC

- program modelled as transition system
 - *state*: *pc* and program variables
 - derived from control-flow graph
 - added safety properties as extra nodes
- program unfolded up to given bounds
- unfolded program optimized to reduce blow-up
 - constant propagation
 - forward substitutions } crucial

```
int getPassword() {  
    char buf[4];  
    gets(buf);  
    return strcmp(buf, "ML");  
}  
  
void main(){  
    int x=getPassword();  
    if(x){  
        printf("Access Denied\n");  
        exit(0);  
    }  
    printf("Access Granted\n");  
}
```

Software BMC

- program modelled as transition system
 - *state*: *pc* and program variables
 - derived from control-flow graph
 - added safety properties as extra nodes
- program unfolded up to given bounds
- unfolded program optimized to reduce blow-up
 - constant propagation
 - forward substitutions } crucial
- front-end converts unrolled and optimized program into SSA

```
int getPassword() {  
    char buf[4];  
    gets(buf);  
    return strcmp(buf, "ML");  
}
```

```
void main(){  
    int x=getPassword();  
    if(x){  
        printf("Access Denied\n");  
        exit(0);  
    }  
    printf("Access Granted\n");  
}
```

```
g1 = x1 == 0  
a1 = a0 WITH [i0:=0]  
a2 = a0  
a3 = a2 WITH [2+i0:=1]  
a4 = g1 ? a1 : a3  
t1 = a4[1+i0] == 1
```

Software BMC

- program modelled as transition system
 - *state*: *pc* and program variables
 - derived from control-flow graph
 - added safety properties as extra nodes
- program unfolded up to given bounds
- unfolded program optimized to reduce blow-up
 - constant propagation
 - forward substitutions } crucial
- front-end converts unrolled and optimized program into SSA
- extraction of *constraints C* and *properties P*
 - specific to selected SMT solver, uses theories
- satisfiability check of $C \wedge \neg P$

```
int getPassword() {  
    char buf[4];  
    gets(buf);  
    return strcmp(buf, "ML");  
}
```

```
void main(){  
    int x=getPassword();  
    if(x){  
        printf("Access Denied\n");  
        exit(0);  
    }  
    printf("Access Granted\n");  
}
```

$$C := \left[\begin{array}{l} g_1 := (x_1 = 0) \\ \wedge a_1 := store(a_0, i_0, 0) \\ \wedge a_2 := a_0 \\ \wedge a_3 := store(a_2, 2 + i_0, 1) \\ \wedge a_4 := ite(g_1, a_1, a_3) \end{array} \right]$$

$$P := \left[\begin{array}{l} i_0 \geq 0 \wedge i_0 < 2 \\ \wedge 2 + i_0 \geq 0 \wedge 2 + i_0 < 2 \\ \wedge 1 + i_0 \geq 0 \wedge 1 + i_0 < 2 \\ \wedge select(a_4, i_0 + 1) = 1 \end{array} \right]$$

Software BMC Applied to Security

```
int getPassword() {  
    char buf[4];  
    gets(buf);  
    return strcmp(buf, "SMT");  
}
```

```
void main(){  
    int x=getPassword();  
    if(x){  
        printf("Access Denied\n");  
        exit(0);  
    }  
    printf("Access Granted\n");  
}
```

buffer overflow attack

SSA & loop unrolling

```
sp0,sp1,sp2:BITVECTOR(8);  
ip:BITVECTOR(8);  
m0,m1,m2,m3,m4,m5 : ARRAY BITVECTOR(8) OF BITVECTOR(8);  
in : ARRAY INT OF BITVECTOR(8);  
ASSERT sp1 = BVSUB(8,sp0,0bin100);  
ASSERT m1 = m0 WITH [sp1] := in[1];  
ASSERT m2 = m1 WITH [BVPLUS(8,sp1,0bin1)] := in[2];  
ASSERT m3 = m2 WITH [BVPLUS(8,sp1,0bin10)] := in[3];  
ASSERT m4 = m3 WITH [BVPLUS(8,sp1,0bin11)] := in[4];  
ASSERT m5 = m4 WITH [BVPLUS(8,sp1,0bin100)] := in[5];  
ASSERT sp2 = BVPLUS(8,sp1,0bin100);  
ASSERT ip = m5[sp2];  
ASSERT NOT ip = m0[sp0];  
CHECKSAT;
```

4-character array *buf*

We wish to determine whether it is possible to set *ip* to a value that we choose instead of the location of the if statement

reclaim the memory occupied by *buf*

ip is loaded with the location pointed to by *sp*

Verifying Multi-threaded Programs

Idea: iteratively generate all possible interleavings and call the BMC procedure on each interleaving

- **symbolic** model checking: on each individual interleaving
- **explicit state** model checking: explore all interleavings

```
void *threadA(void *arg) {  
    lock(&mutex);  
    x++;  
    if (x == 1) lock(&lock);  
    unlock(&mutex); (CS1)  
    lock(&mutex); (CS3)  
    x--;  
    if (x == 0) unlock(&lock);  
    unlock(&mutex);  
}
```

Deadlock

```
void *threadB(void *arg) {  
    lock(&mutex);  
    y++;  
    if (y == 1) lock(&lock); (CS2)  
    lock(&mutex);  
    y--;  
    if (y == 0) unlock(&lock);  
    unlock(&mutex);  
}
```

Lazy exploration of the Reachability Tree

syntax-directed
expansion rules

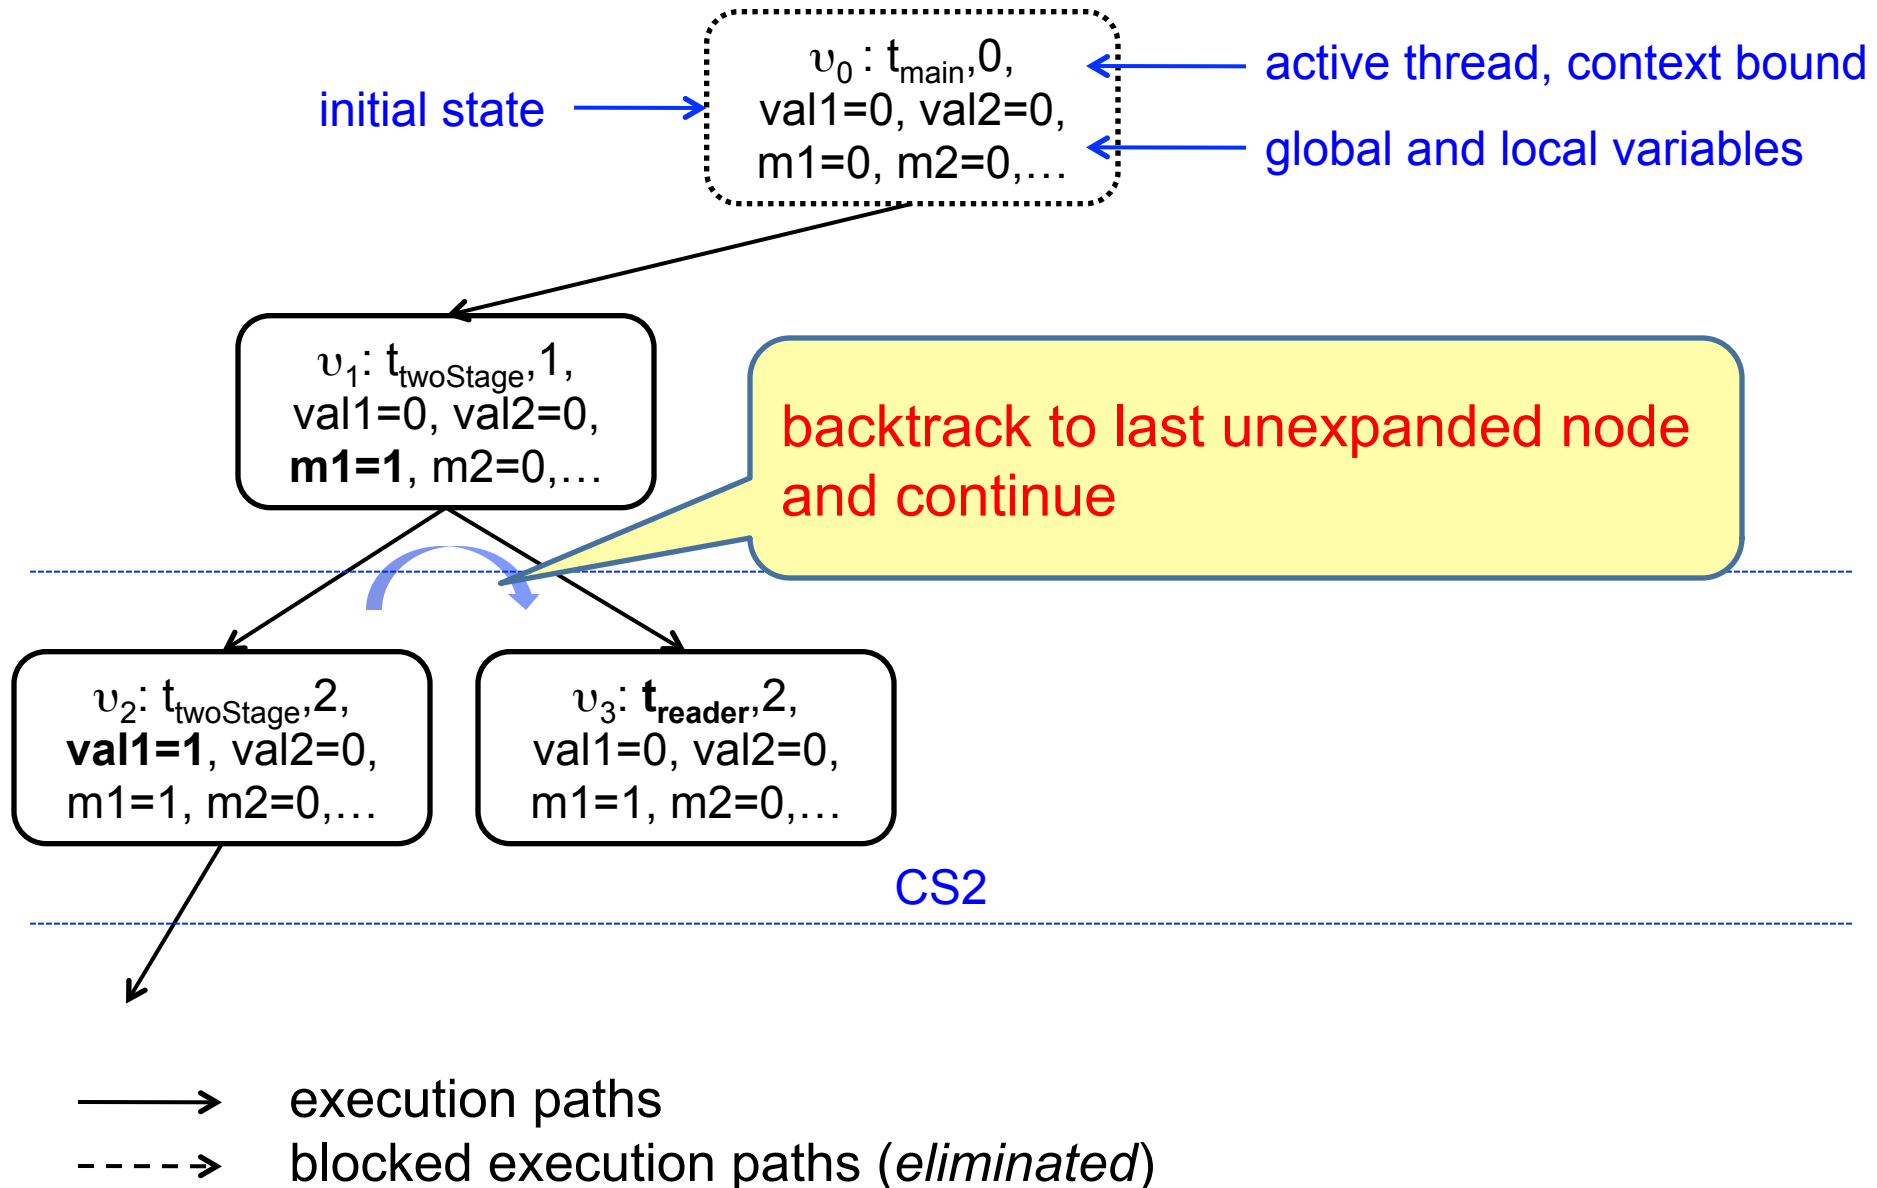

CS1

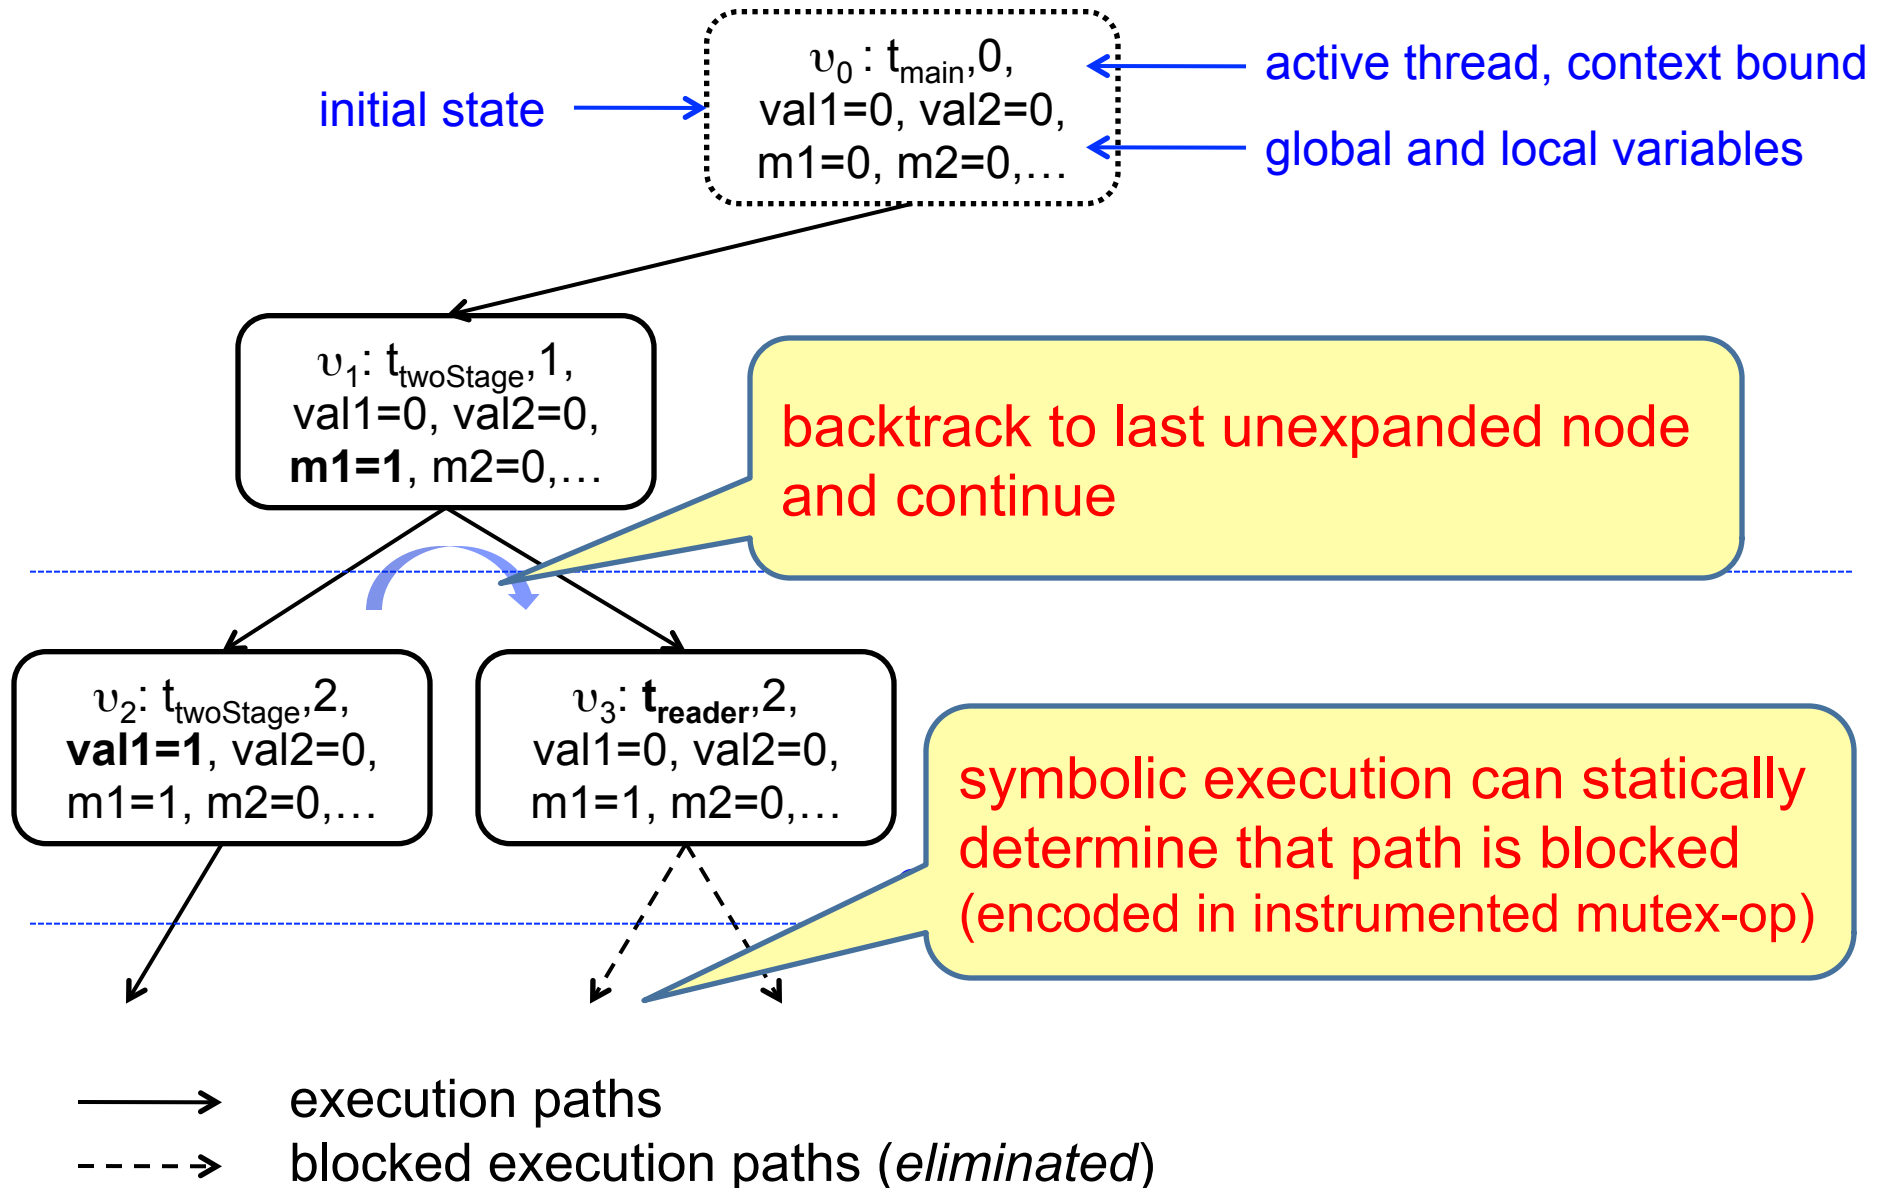

interleaving completed, so
call single-threaded BMC

→ execution paths

Lazy exploration of the Reachability Tree

Lazy exploration of the Reachability Tree

Lazy exploration of the Reachability Tree

execution paths

blocked execution paths (*eliminated*)

BMC / SE for Coverage Test Generation

- Translate the program to an **intermediate representation** (IR)
- Add goals indicating the **coverage**
 - *location, branch, decision, condition and path*
- **Symbolically** execute IR to produce an SSA program
- Translate the resulting SSA program into a **logical formula**
- Solve the formula iteratively to cover different goals
- Interpret the solution to figure out the **input conditions**
- Spit those input conditions out as a test case

Coverage Test Generation for Security

```
x = input();  
if (x >= 10)  
{  
    if (x < 100)  
        vulnerable_code();  
    else  
        func_a();  
}  
else  
    func_b();
```

Coverage Test Generation for Security

```
x = input();  
if (x >= 10)  
{  
  if (x < 100)  
    vulnerable_code();  
  else  
    func_a();  
}  
else  
  func_b();
```

Coverage Test Generation for Security

```
x = input();  
if (x >= 10)  
{  
  if (x < 100)  
    vulnerable_code();  
  else  
    func_a();  
}  
else  
  func_b();
```

State AA
Variables x = ???
Constraints x < 10

State AB
Variables x = ???
Constraints x >= 10

Coverage Test Generation for Security

```
x = input();  
if (x >= 10)  
{  
  if (x < 100)  
    vulnerable_code();  
  else  
    func_a();  
}  
else  
  func_b();
```

Coverage Test Generation for Security

```
x = input();  
if (x >= 10)  
{  
  if (x < 100)  
    vulnerable_code();  
  else  
    func_a();  
}  
else  
  func_b();
```

BMC / SE for Coverage Test Generation

- Pros:
 - Precise
 - no false positive (with correct environment model)
 - produces directly-actionable inputs
- Cons:
 - Not easily scalable
 - ▷ constraint solving is NP-complete
 - ▷ state and path explosion
- Combining Approaches
 - Symbolic Execution, Fuzzing, and Sanitizers

Research Goals in Program Analysis and Cyber-Security

leverage **program analysis/synthesis** to
improve **coverage** and reduce **verification**
time for finding **vulnerabilities** in software

leverage **program analysis/synthesis** to
achieve **correct-by-construction** software
systems considering **security** aspects

Vision for Future Research

Automated Software Verification and Synthesis for UAVs

Automated Software Verification and Synthesis for UAVs

Automated Software Verification and Synthesis for UAVs

Automated Software Verification and Synthesis for UAVs

synthesis failed

Automated Software Verification and Synthesis for UAVs

machine learning for achieving a
correct-by-construction
implementation (program repair)

Synthesizing Control Software in UAVs

- **Counterexample guided induction synthesis** automates the controller design that is **correct-by-construction**

stability, safety, performance
specifications

$$C(z) = \frac{a_2 z^2 + a_1 z + a_0}{b_2 z^2 + b_1 z + b_0}$$

Synthesizing Stable Controllers in UAVs

- Step responses for a **closed-loop control system** with **FWL effects** and for each synthesize iteration

A digital system is **stable** *iff* all of its poles are inside the z-plane unitary circle

Trajectory Planning for UAVs

- What is the shortest trajectory for this UAV?

Trajectory Planning for UAVs

- What is the shortest trajectory for this UAV?

system's dynamics

Trajectory Planning for UAVs

- How to find a solution that satisfies the constraints and minimizes the path length?

Path Optimization Problem

- The search space is delimited by a rectangle
- Obstacles are modeled by circles

$$J(L) = \sum_{i=1}^{n-1} \|P_{i+1} - P_i\|_2$$

$$\begin{aligned} \min_L \quad & J(L), \\ \text{s.t.} \quad & p_{i\lambda}(L) \notin \mathbb{O} \\ & p_{i\lambda}(L) \in \mathbb{E} \\ & i = 1, \dots, n-1 \end{aligned}$$

no intersection between the path and obstacles

What are the real life attacks to UAVs?

- GPS spoofing

Civilian GPS signals without encrypted signals

What are the real life attacks to UAVs?

- GPS spoofing
- No encryption

Encryption is extra implementation
cost for performance and energy

What are the real life attacks to UAVs?

- GPS spoofing
- No encryption
- No authentication

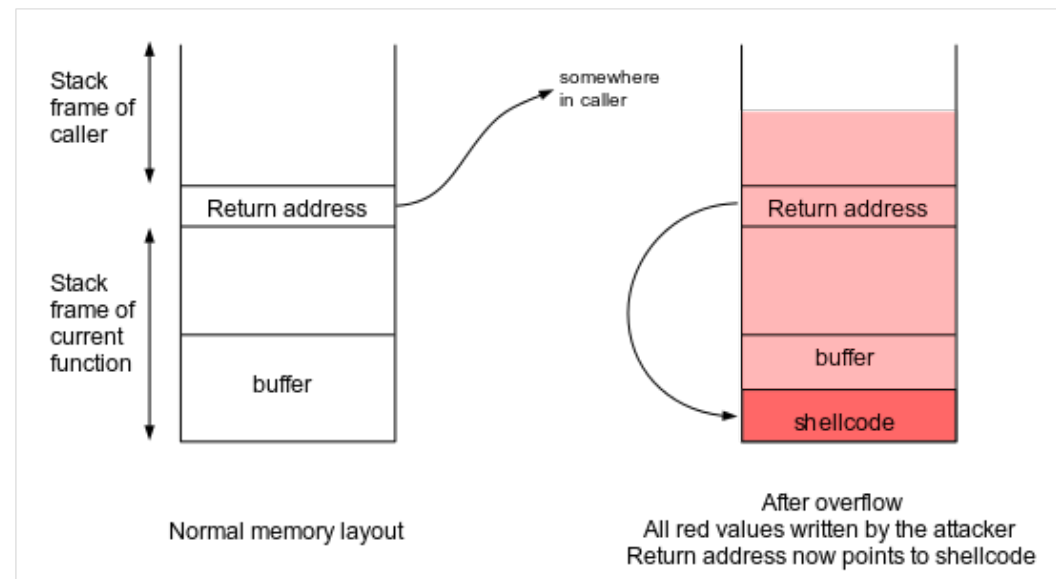

Vulnerability: “Insufficient connection protection”

What are the real life attacks to UAVs?

- GPS spoofing
- No encryption
- No authentication
- Large packets causing stack overflow

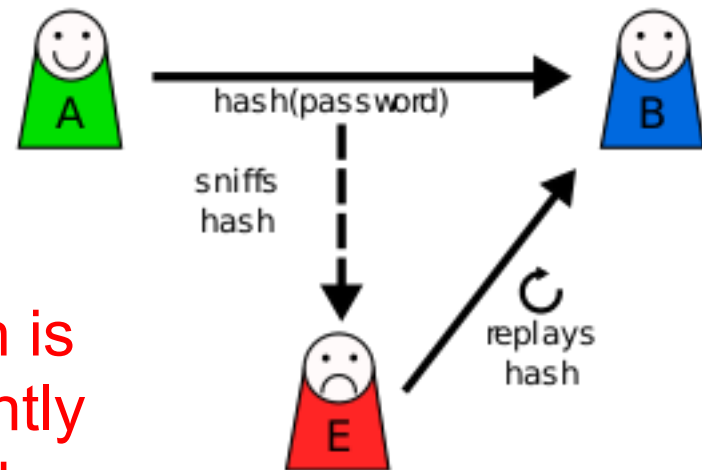

cause the program to
crash or operate
incorrectly

What are the real life attacks to UAVs?

- GPS spoofing
- No encryption
- No authentication
- Large packets causing stack overflow
- Replay attack

valid data transmission is
maliciously or fraudulently
repeated or delayed

What are the real life attacks to UAVs?

- GPS spoofing
- No encryption
- No authentication
- Large packets causing stack overflow
- Replay attack
- Etc

Research Mission

Automated **verification** and **synthesis** to ensure the
software security in **UAVs**

**Methods, algorithms, and
tools to write software
with respect to security**
